

Genome-wide SNPs unravel population structure and variability in the Fijian Black-lip Pearl Oyster

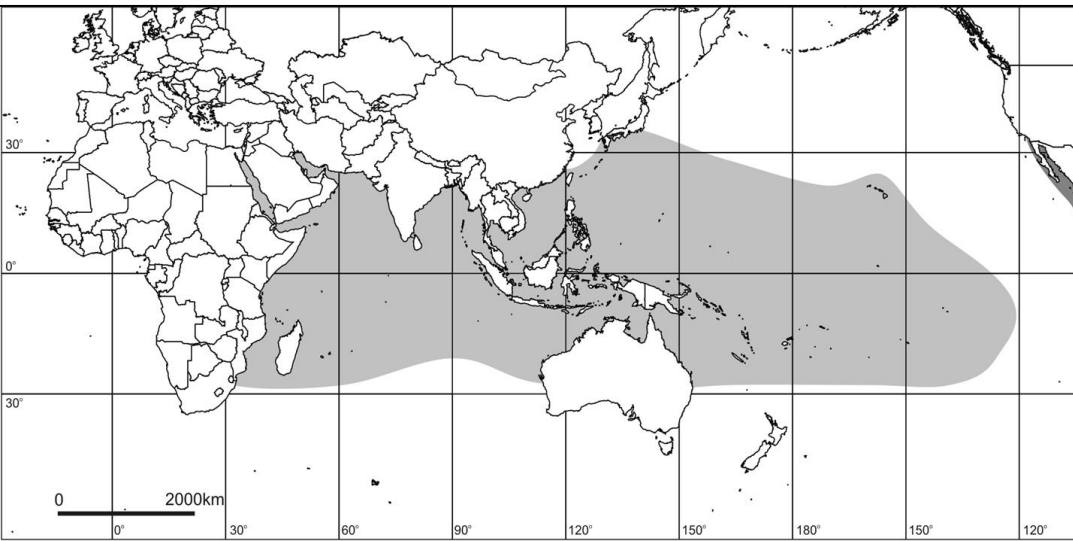

Monal Lal, Dean Jerry, Paul Southgate, Cyprien Bosserelle & Kyall Zenger

Overview

- Black-lip Pearl Oyster and Fijian cultured pearl industry.
- Research problem/knowledge gaps.
- Study overview and methods.
- Results and future directions.

Pinctada margaritifera (L.)

- Broad Indo-Pacific natural distribution, 0-20m, reef.
- ~120 mm DVH, ~ 100 mm DVM. 26-29 °C, 28 – 32 ‰.
- Primary species for aquaculture in the Pacific Islands.
- Broadcast spawner, 40-50 million eggs.

Pinctada margaritifera (L.)

Traditional black and coloured “Fiji” pearls

Pearl oyster aquaculture in Fiji

- *Pinctada margaritifera* is the main species.
- Most valuable aquaculture commodity: \approx 13 million USD annually.
- \sim 7 farms, reliant on mainly wild-caught + hatchery produced spat.
- Farm expansion and establishment set to grow the industry.

Research problems/knowledge gaps

- Wild oyster stocks reduced.
- No fishery management policy.
- Population genetic status unknown.
- Biological data needed for conservation and aquaculture efforts.
- Population genomic tools will provide the answer!

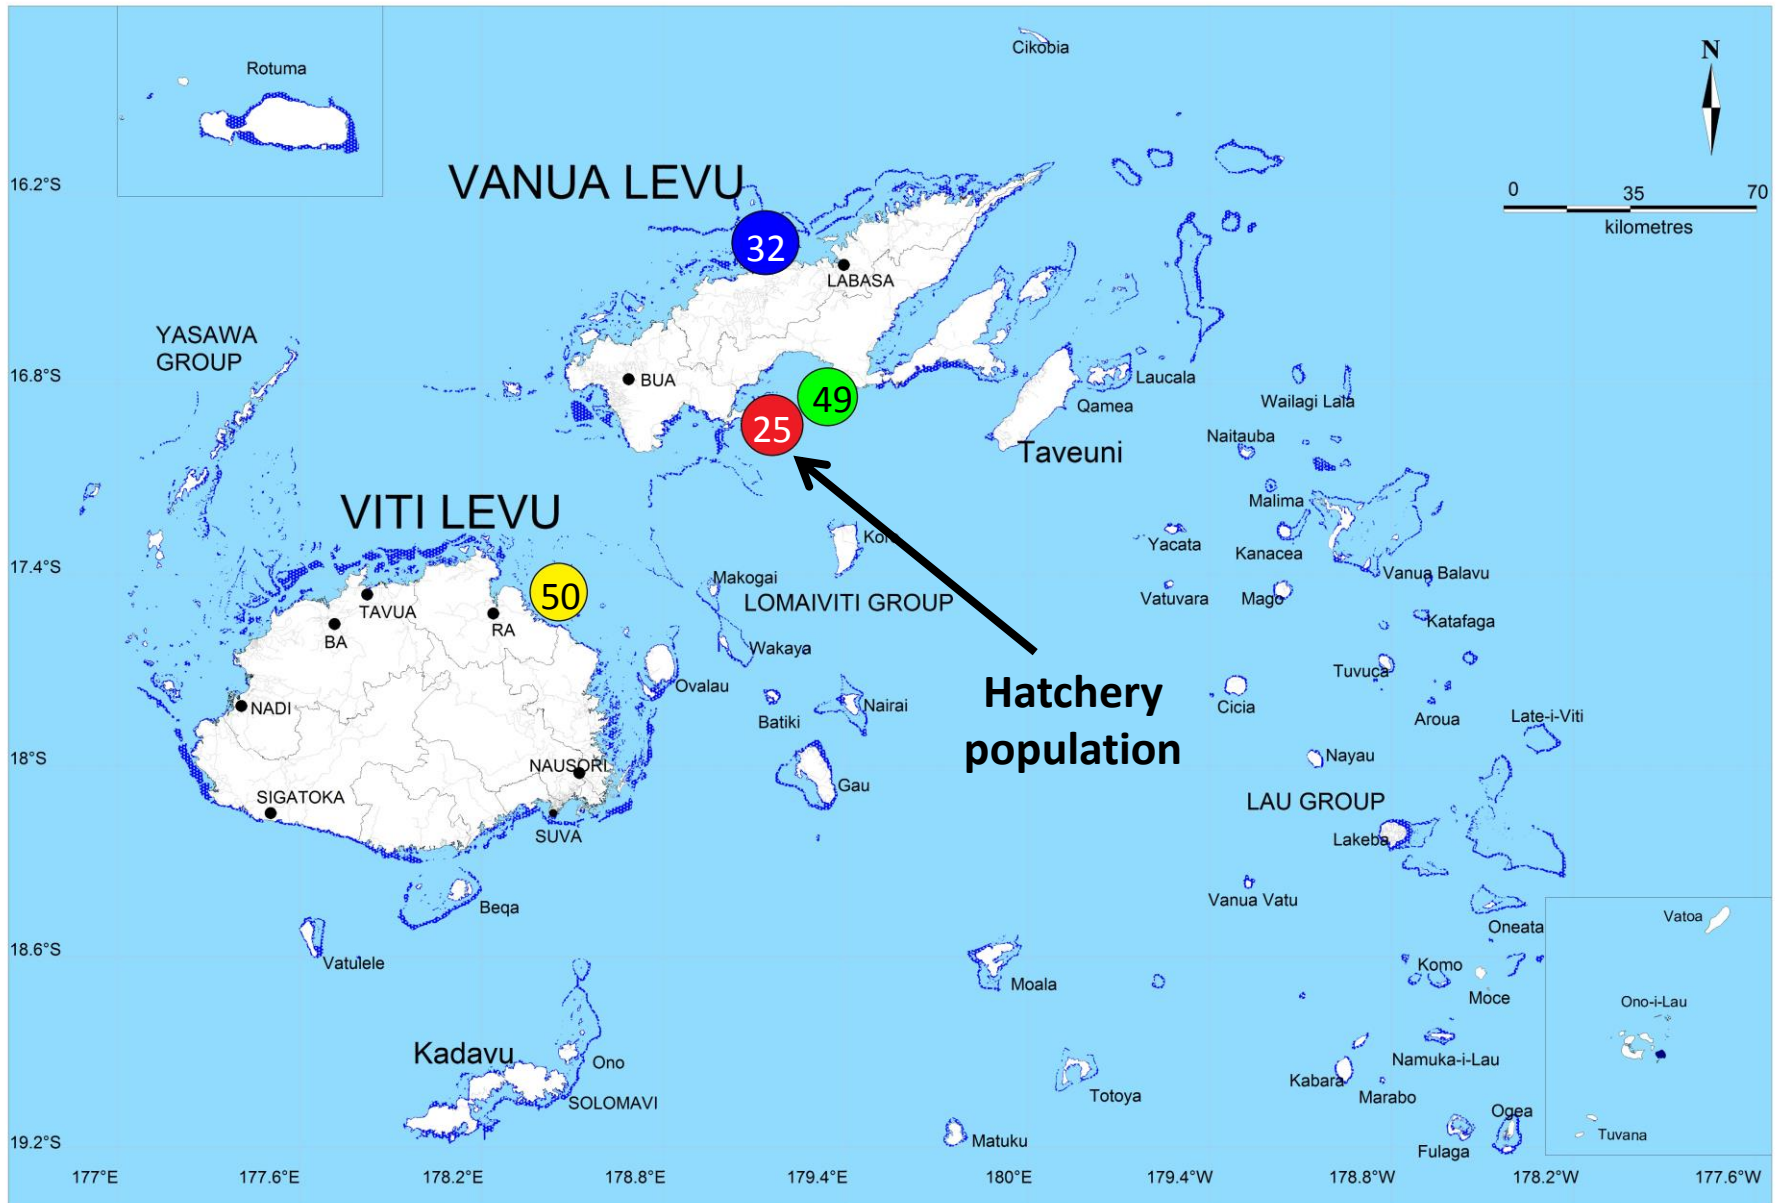

Study overview

Specific aims:

- For Fijian *P. margaritifera* develop genome-wide SNPs to determine:
 - Genetic diversity levels.
 - Population structure.
 - Relatedness and gene flow.
 - Investigate colour morphotypes.
 - Formulate recommendations for management of fishery and sustainable aquaculture.

Methods: tissue sampling.

Methods: population genomics

ddRADseq:
Genome-wide
SNP markers

- ▶ Differentiation
- ▶ Gene flow
- ▶ Structure
- ▶ Diversity

- ▶ ARLEQUIN
- ▶ GenePop
- ▶ GENETIX
- ▶ *adegenet*
- ▶ *DiveRsity*
- ▶ NeESTIMATOR
- ▶ NETVIEW
- ▶ BayeScan
- ▶ LOSITAN

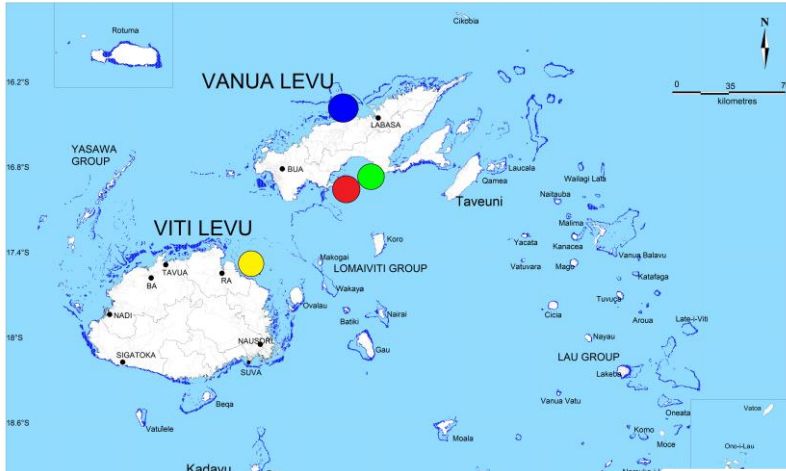

Results: population genomics

- 5,234 genome-wide SNPs discovered.
- Low levels of genetic differentiation (average $F_{st} = 0.042$).
- $N_e > 192$ for all wild populations.
Hatchery $N_e = 6.1$.
- Outlier analyses detected ~ 100 SNPs between colour morphs.

Results: population genomics

DAPC : 4 populations (5,234 SNPs)

PCA eigenvalues

DA eigenvalues

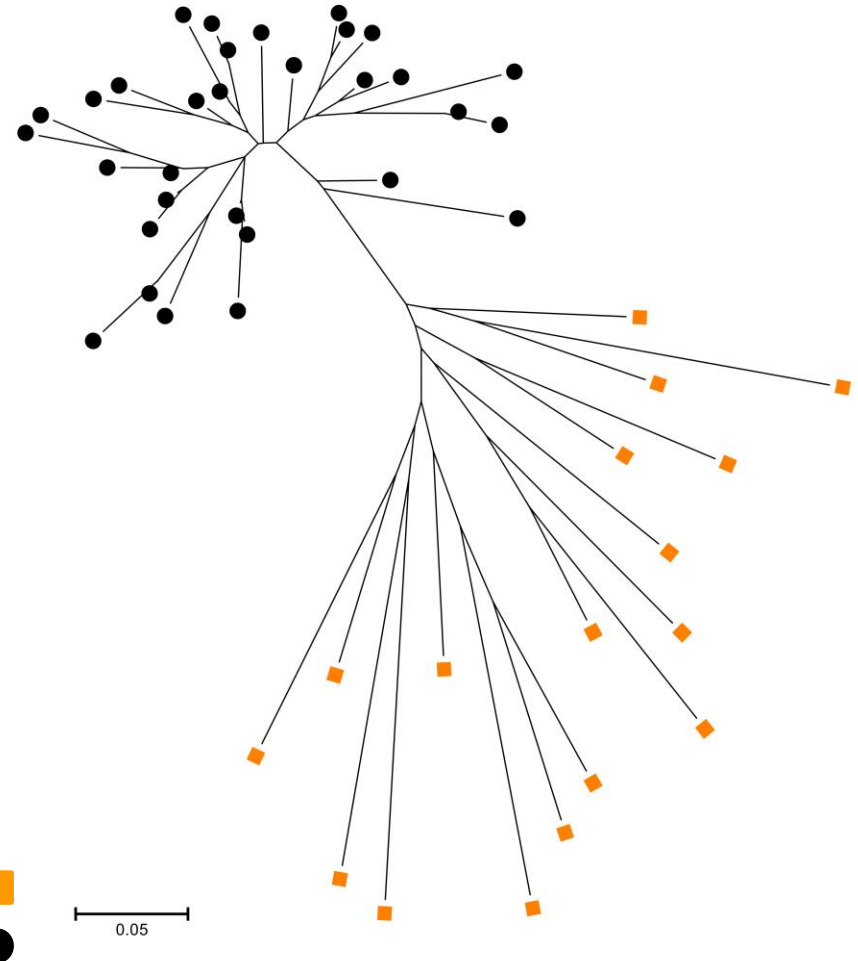

NETVIEW : 4 populations, 156 individuals (k-NN = 40, 5,234 SNPs)

Results: colour morphs

5,243 SNPs

100 outlier SNPs

Conclusions and future directions

- Genome-wide SNPs revealed panmixia for *P. margaritifera* within Fiji.
- High utility of SNPs to detect population structure and differentiation
- Outlier testing able to differentiate between tissue colour morphotypes.
- Sound fishery management possible given informativeness of dataset.
